stg — EKS cluster svp-stg

ap-southeast-1 · 2 AZs · one NAT gateway, in the first AZ, for every private subnet · managed node group Spot, one icon per AZ · RDS single-AZ (AWS picks the AZ; drawn in the first) · one NLB across all public subnets, made by the AWS Load Balancer Controller · EBS volumes in the AZ of their pod's node

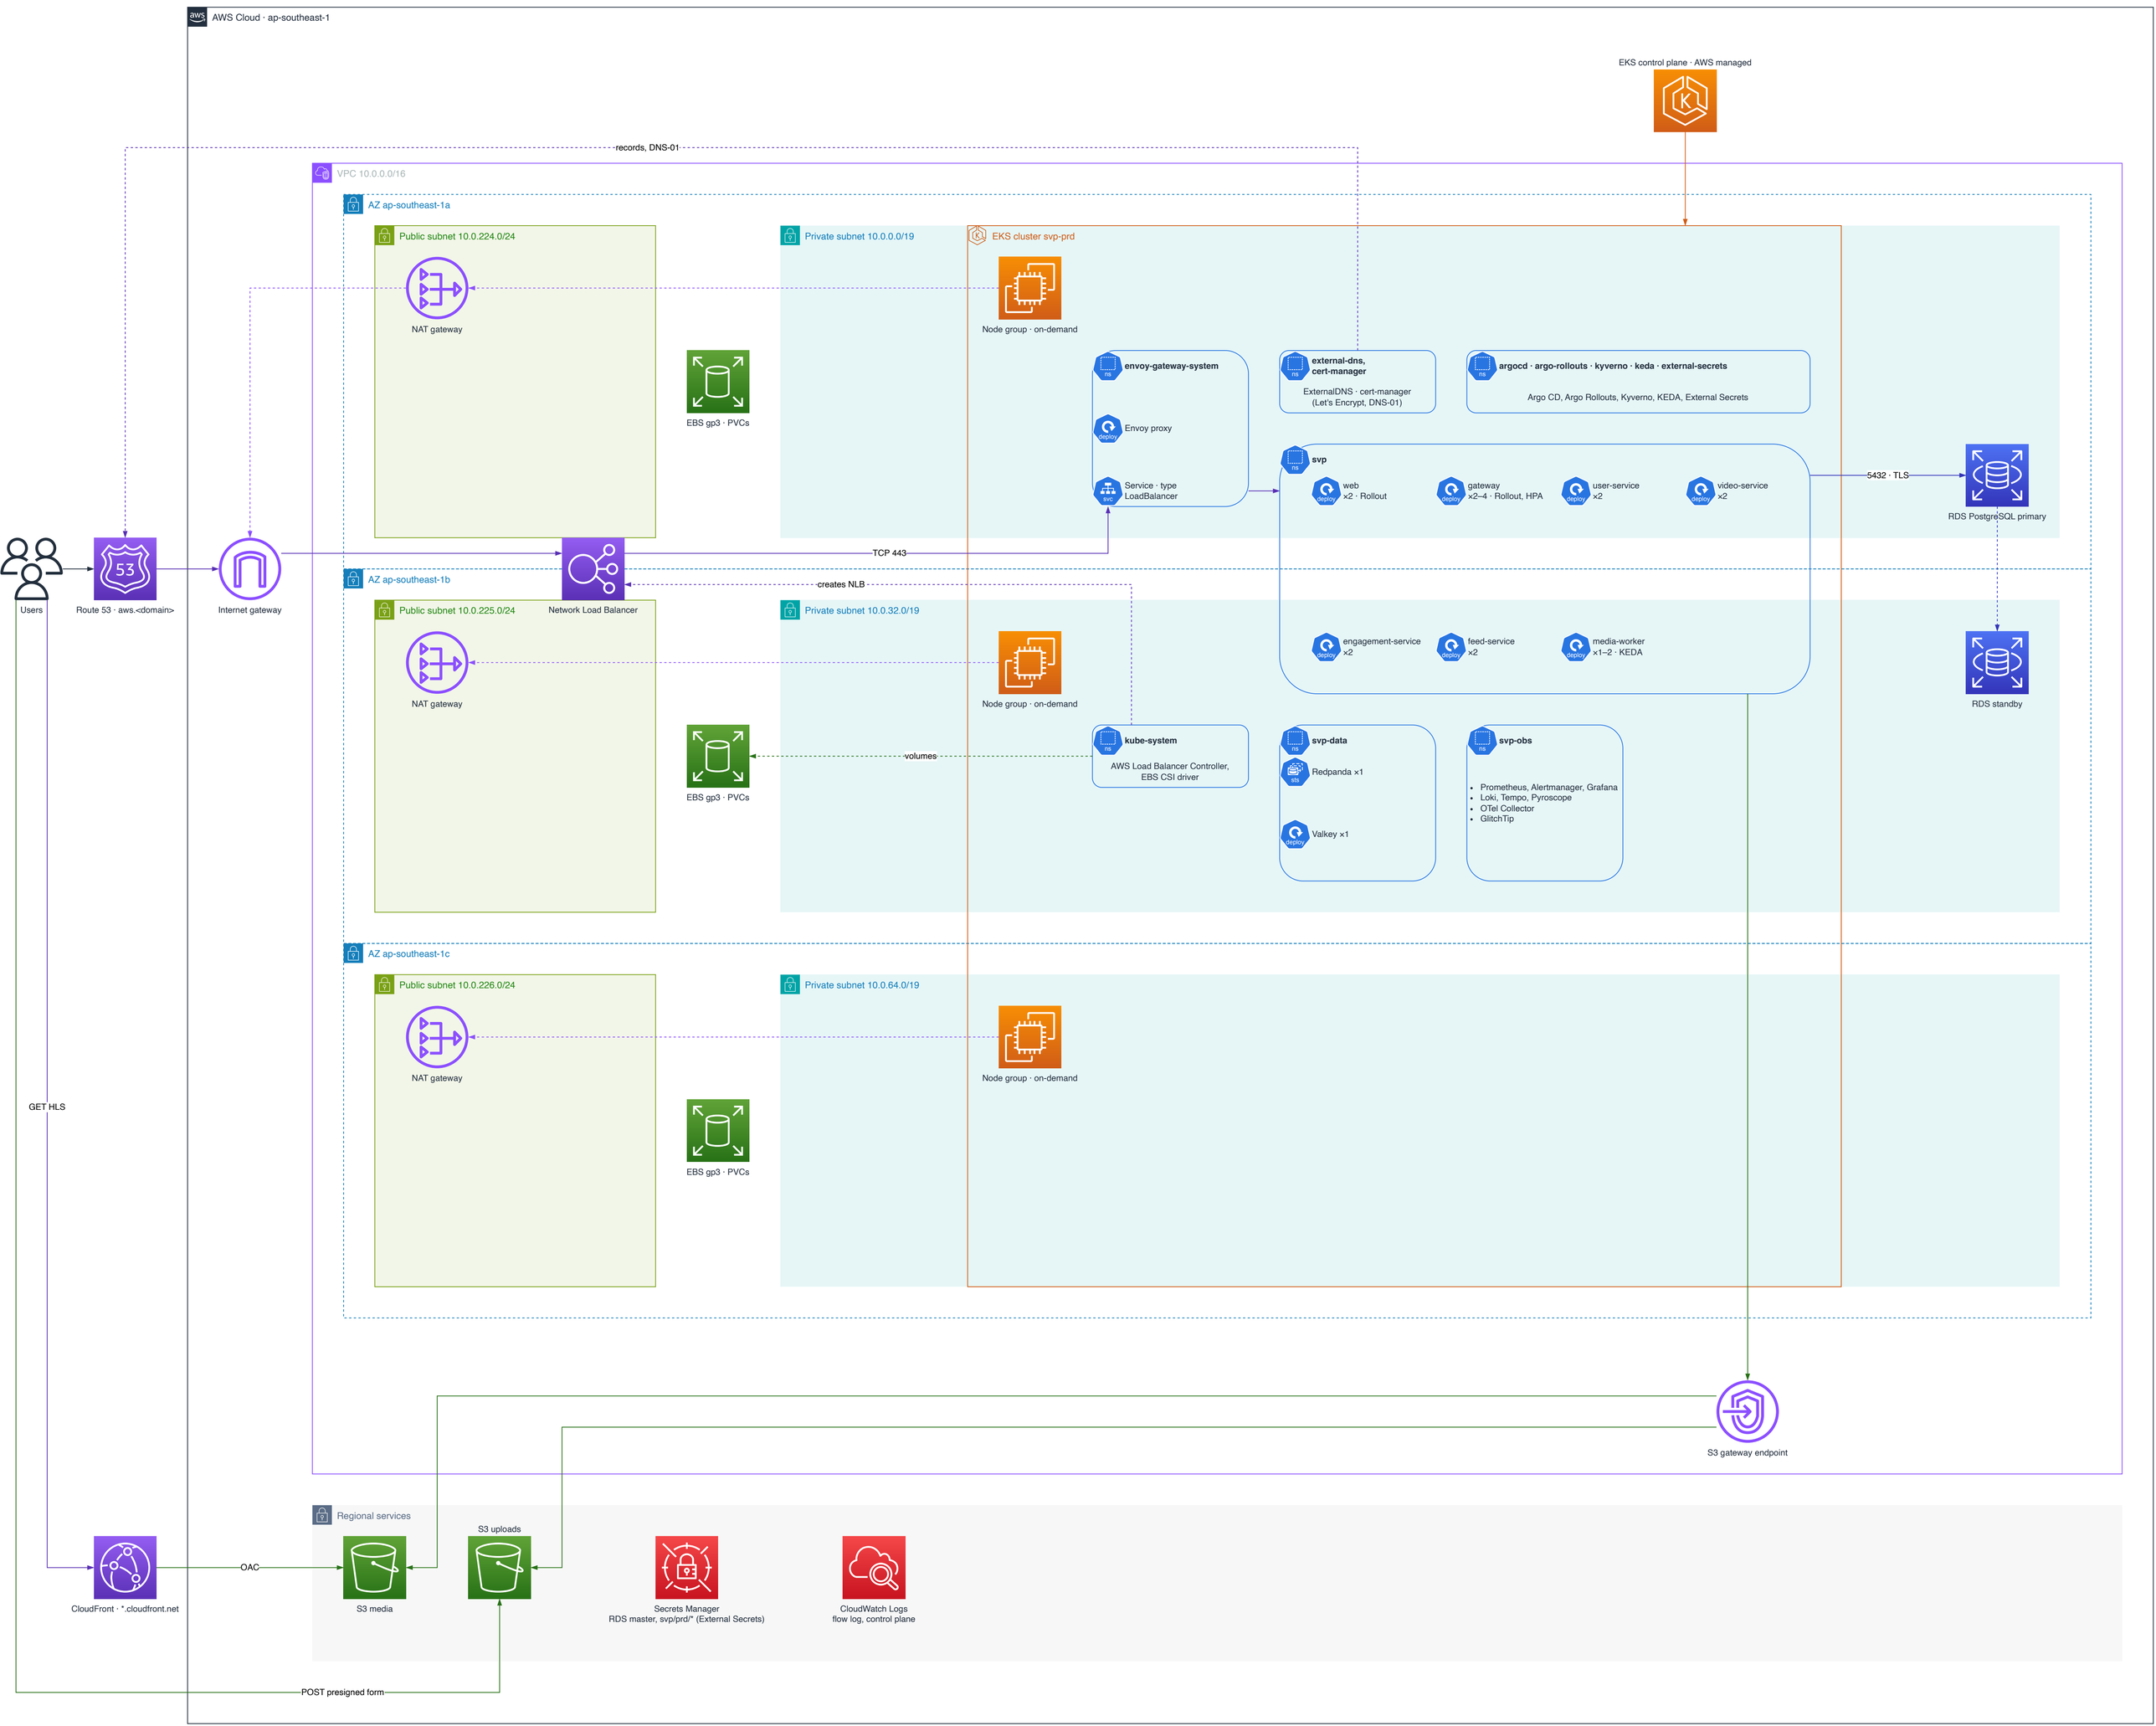

Kubernetes: a frame per namespace, an icon per workload with its replicas · the scheduler puts each pod on any node of any AZ, so the row of a frame or an icon says nothing about where its pods run (svp is drawn across the first two AZs to show it) · third-party tools as text · EKS add-ons (CoreDNS, kube-proxy, VPC CNI) not drawn

prd — EKS cluster svp-prd

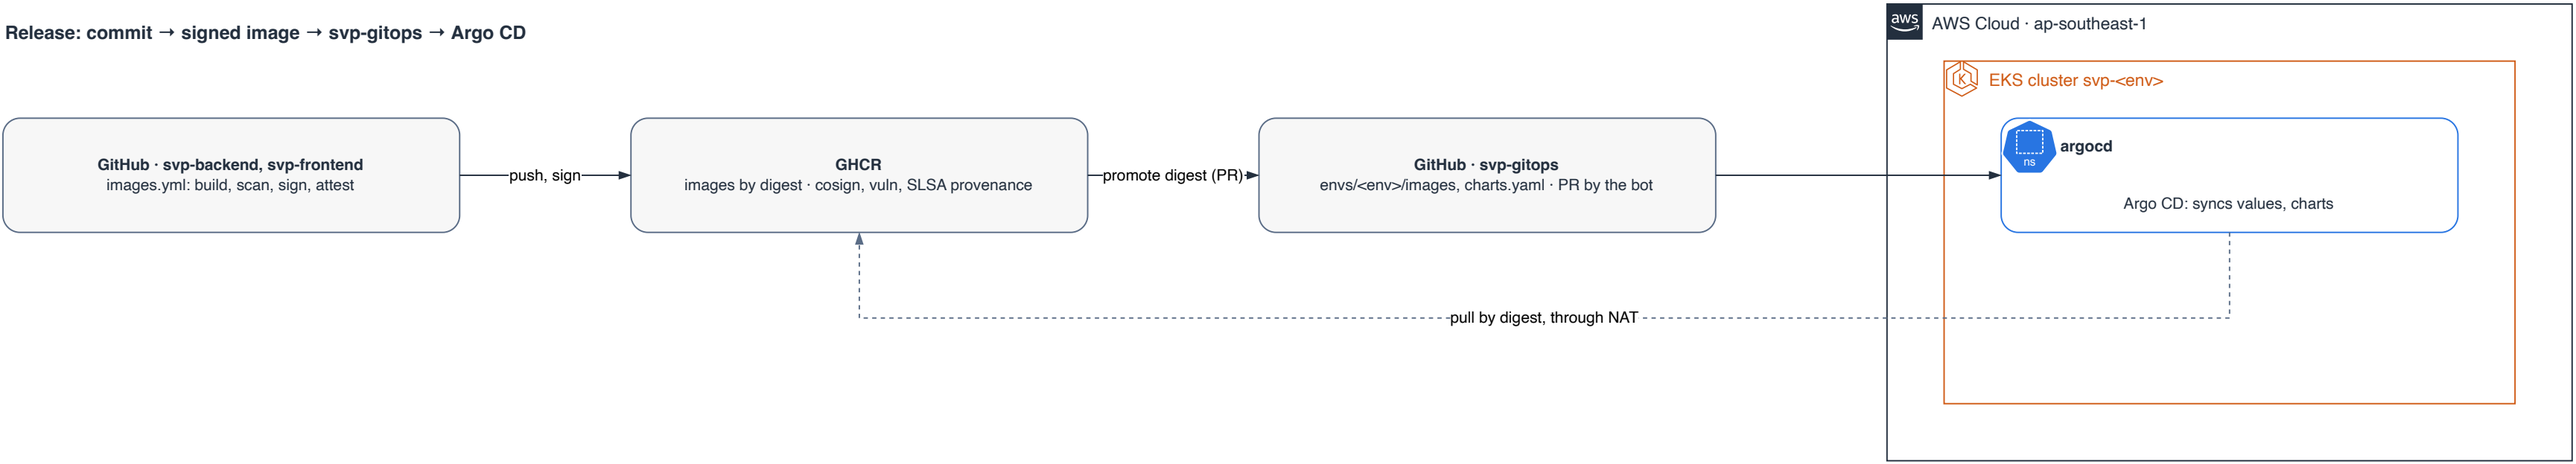

ap-southeast-1 · 3 AZs · one NAT gateway per AZ · managed node group on-demand, one icon per AZ · RDS Multi-AZ primary/standby (AWS picks the AZs; drawn in the first two) · one NLB across all public subnets, made by the AWS Load Balancer Controller · EBS volumes in the AZ of their pod's node

Kubernetes: a frame per namespace, an icon per workload with its replicas · the scheduler puts each pod on any node of any AZ, so the row of a frame or an icon says nothing about where its pods run (svp is drawn across the first two AZs to show it) · third-party tools as text · EKS add-ons (CoreDNS, kube-proxy, VPC CNI) not drawn
